

***SCENARIO F: WOMAN OF UNKNOWN HIV STATUS WHO PRESENTS IN LABOUR***

If available, a rapid HIV serologic (antibody) test should be administered as soon as feasible. If the rapid test result is positive for HIV infection and she is still in labour, she should be managed as in scenario E. If the test result becomes available only after she has delivered – either because she delivered before the test was administered, or rapid testing was unavailable and therefore standard serologic testing was used – then she should be managed as in scenario G, below.
